

United States Department of Agriculture  
Agricultural Marketing Service | National Organic Program  
Document Cover Sheet

<https://www.ams.usda.gov/rules-regulations/organic/national-list/petitioned>

Document Type:

**National List Petition or Petition Update**

A petition is a request to amend the USDA National Organic Program's National List of Allowed and Prohibited Substances (National List).

Any person may submit a petition to have a substance evaluated by the National Organic Standards Board (7 CFR 205.607(a)).

Guidelines for submitting a petition are available in the NOP Handbook as NOP 3011, National List Petition Guidelines.

Petitions are posted for the public on the NOP website for Petitioned Substances.

**Technical Report**

A technical report is developed in response to a petition to amend the National List. Reports are also developed to assist in the review of substances that are already on the National List.

Technical reports are completed by third-party contractors and are available to the public on the NOP website for Petitioned Substances.

Contractor names and dates completed are available in the report.

# Sodium Citrate

## Crops

1

2

### Identification of Petitioned Substance

3

4 **Chemical Names:**

6132-04-3; 6858-44-2

5 Monosodium citrate, disodium citrate, trisodium  
6 citrate, sodium citrate

**Other Codes:**

7 **Other Name:**

Pubchem ID: 6224; InChI Key:  
HRXKRNGNAMMEHJ-UHFFFAOYSA-K

8 Sodium dihydrogen citrate, disodium hydrogen  
9 citrate, Trisodium 2-hydroxypropane-1,2,3-  
10 tricarboxylate

InChI: InChI=1S/C6H8O7.3Na/c7-3(8)1-  
6(13,5(11)12)2-4(9)10;;;/h13H,1-  
2H2,(H,7,8)(H,9,10)(H,11,12);;/q;3\*+1/p-3  
Canonical SMILES: C(C(=O)[O-])C(CC(=O)[O-]  
)](C(=O)[O-])O.[Na+].[Na+].[Na+]

11 **Trade Names:**

12 Citrosodina, Natrocitral, Citnatin, Orange Eno

EC Number: 200-675-3, 218-618-2

**CAS Numbers:**

18996-35-5;  
144-33-2;  
68-04-2;

FEMA Number: 3026

ICSC Number: 1218

RTECS Number: GE8300000

UNII: RS7A450LGA

13

### Summary of Petitioned Use

14

15 Sodium citrate is used as an anticoagulant in the collection of slaughterhouse blood. Slaughterhouse blood is  
16 used to make the soil amendment, blood meal. Slaughterhouse blood can be processed in different ways to make  
17 blood meal. The petition requests the addition of sodium citrate to the National List (§ 205.601), allowed for use  
18 in crop production to prevent animal blood coagulation after collection and during processing of blood for  
19 production of blood meal.

20

### Characterization of Petitioned Substance

21

22 **Composition of the Substance:**

23 Sodium citrate is a soluble white powder. It has many uses. One of which is as an anticoagulant in the collection  
24 and processing of animal blood. Sodium citrate treated blood may be used for production of the soil amendment,  
25 blood meal. Animal blood meal is allowed in organic crop production as a soil amendment.

26 **Source or Origin of the Substance:**

27 Sodium citrate is a salt derivative of citric acid. Citric acid is naturally occurring. Sodium citrate is  
28 chemically produced by the same process as citric acid (NOP, 2015). Commercially, citric acid is produced  
29 microbiologically mostly from the sugar refinery byproduct, molasses. The mycelial fungus *Aspergillus*  
30 *niger* or *Candida* spp. yeasts are frequently used for these fermentation processes. Citric acid from  
31 fermentation is neutralized with sodium hydroxide and crystalized in the production of sodium citrate.  
32 Sodium citrate can be produced microbiologically, directly from cultures of the yeast *Yarrowia lipolytica*,  
33 since this organism can tolerate a higher pH (Kamzolova et al., 2015).

34 Sodium citrate is routinely added to blood as it is removed from animal carcasses during processing. The  
35 addition of sodium citrate keeps blood flowing and minimizes extensive cleaning of clotted blood from  
36 extraction and collection equipment. Anticoagulants have been considered incidental to blood meal  
37 production and part of the standard identity for blood, since a substantial portion of added sodium citrate  
38 is removed during manufacturing. Furthermore, it may not be reliably possible for manufacturers to

39 determine if anticoagulants have been added to blood for blood meal production (Bungum, 2017). Animals  
40 can be bled, and their blood collected without the addition of sodium citrate. This practice is not common  
41 for large animal processing plants (Food Safety Authority of Ireland, 2013; NCPS Board of Consultants and  
42 Engineers, 2016).

### 43 **Properties of the Substance:**

44 Sodium citrate, the sodium salt derivative of citric acid, is a crystalline white powder with a melting point  
45 of  $>300^{\circ}\text{C}$ . Its molecular formulae are: anhydrous:  $\text{C}_6\text{H}_5\text{O}_7\text{Na}_3$ ; hydrated:  $\text{C}_6\text{H}_5\text{O}_7\text{Na}_3 \cdot n\text{H}_2\text{O}$  ( $n = 2$  or  $5$ ) or  
46  $\text{C}_6\text{H}_5\text{Na}_3\text{O}_7$  or  $\text{C}_6\text{H}_5\text{O}_7 \cdot 3\text{Na}$ . It has a molecular weight of 258.08 grams/mole. A two-dimensional  
47 structure of sodium citrate is provided in Figure 1. Previous technical reviews for citric acid and sodium  
48 citrate are available on the NOP website (NOP, 2015).

49  
50 Figure 1 2D Sodium Citrate Structure  
51 (PubChem, 2017)

### 52 **Specific Uses of the Substance:**

53 Sodium citrate is routinely used as an anticoagulant for blood collection during slaughtering and  
54 processing of livestock. It may be applied to the sticking knife, to improve blood flow during bleeding or  
55 added to collection or storage tanks to improve stability. Blood products are separated, cooked and dried  
56 into powder at the meat processing plant or further processing plants. Storage and transfer of blood  
57 requires refrigeration. Blood meal, a by-product of the animal slaughtering industry is used in organic crop  
58 production as a soil amendment (Yunta et al., 2013; §205.203(c)). Several methods are in use commercially  
59 for production of blood meal. These differ in clotting or no clotting, drying steps and the separation of red  
60 blood cells. Some examples are batch dried, ring dried and spray dried rendering. Batch dry rendering is  
61 simple cooking of whole blood with indirect high-pressure steam to remove moisture. Ring dried  
62 rendering requires coagulation and separation of the coagulated blood from fluids. The coagulum is  
63 separately dried. In spray drying, which requires the use of sodium citrate, flowing blood treated with  
64 anticoagulant is sprayed into a warm chamber where it instantly becomes a fine powder. Drying method  
65 affects the characteristics and quality of the final product. With meat inspection, blood meal can also be  
66 used for conventional human and animal nutrition. In addition to simply drying clotted whole blood,  
67 blood may be fractionated during processing to separate red blood cells from plasma or remove specific  
68 higher valued products before dried meal is produced.

69

### 70 **Approved Legal Uses of the Substance:**

71 Sodium citrate has been verified to be of low concern based on experimental and modeled data for use as a  
72 chelating agent (anticoagulant), a preservative, an antioxidant, a processing aid and an additive ([EPA Safer  
73 chemical ingredients list](#)). Sodium citrate is included in the FDA list of substances generally regarded as  
74 safe. It is the sodium salt of citric acid prepared by fermentation and neutralization of citric acid with  
75 sodium hydroxide or sodium carbonate. The product occurs as colorless crystals or a white crystalline  
76 powder. It may be prepared in an anhydrous state or may contain two moles of water per mole of sodium  
77 citrate (21 CFR 184.1751). Sodium citrate is listed in the National List as an allowed synthetic for use in  
78 organic handling (§205.605b). The sodium salts of citric acid – monosodium citrate, disodium citrate and tri  
79 sodium citrate – are collectively listed as “sodium citrate.” These substances are used similarly as pH

80 control/buffering agents and stabilizers in food products. The original [technical review](#) found sodium  
81 citrate to be consistent with the OFPA 2119(m) criteria ([NOSB, 2010](#)). Sodium citrate is not allowed for use  
82 in organic crop production.

83

86

87

### 88 **Action of the Substance:**

89 Blood is an important meat animal processing byproduct. [Blood meal](#), a non-synthetic product of animal  
90 byproduct processing, is allowed for use as a soil amendment in organic crop production (205.203(c)).  
91 Approximately 4-5% of live animal weight is collectable blood which contains approximately 10% of  
92 animal protein. When fresh blood is extracted from an animal, fibrinogen in the blood is converted to  
93 fibrin. The presence of fibrin catalyzes the formation of a fibrous network that enmeshes blood cells and  
94 other blood components into a clot. Clotting can be inhibited by vigorous agitation, chilling or by the  
95 addition of anticoagulants. Sodium citrate is an anticoagulant commonly used for collecting blood in  
96 slaughterhouses (Fernando, 1992). Ionic calcium is essential for the conversion of fibrinogen to fibrin.  
97 Sodium citrate acts to chelate or remove available calcium required for the fibrinogen to fibrin conversion  
98 preventing blood coagulation (clotting). In chelation, calcium binds to the dentate carboxyl moieties of  
99 citrate (Fig. 2).

100 Blood can become recalcified through cell breakdown and bacterial degradation. When calcium is available  
101 for fibrinogen to fibrin conversion, clotting resumes. After bleeding warm blood is only stable for  
102 approximately eight hours. Without refrigeration, fresh whole blood must be processed and dried shortly  
103 after bleeding. Even with the addition of sodium citrate, animal byproduct producers reduce whole blood  
104 degradation, bacterial contamination and further clotting by chilling stored blood with stirring prior to  
105 inspection and further downstream processing. This is important, if blood must be transported to another  
106 facility. Chilled whole blood held at 2-3°C is stable for approximately 120 hours which facilitates off site  
107 processing (Labudde Group, 2017; Sjöberg, 2017).

### 108 **Combinations of the Substance:**

109 Sodium citrate is added directly to blood as it is collected during meat animal processing. It may be  
110 dissolved in water and added as a solution to speed its action. Other substances are not generally used in  
111 combination for byproduct meat animal blood processing.

112 <b>Status</b>
-------------------

113

### 114 **Historic Use:**

115 Sodium citrate was first used as an experimental anticoagulant in blood transfusion for dogs in the 1890s  
116 (Mollison, 2000; Hedley-Whyte and Miamed, 2010). By 1915, the minimum amount of sodium citrate  
117 necessary for anticoagulation of blood without side effects had been determined for human use (Lewisohn,  
118 1915). By 1918, the military development of an acceptable procedure for human blood transfusion and  
119 blood storage became a necessity. Sodium citrate at 0.2% was not only safe for humans use, but could be  
120 used for routine transfusion practice and storage of whole blood for up to two weeks (Arthus, 1905;  
121 Lewisohn, 1918). Sodium citrate has been used as an anticoagulant for the collection of slaughterhouse  
122 blood since the late 1800s (Wismer-Pedersen, 1988).

123

**124 Organic Foods Production Act, USDA Final Rule:**

125 Sodium citrate is listed on 205.605(b), synthetics allowed for processed products labeled as organic.

**126 International**

127 **Canada** - Canadian General Standards Board Permitted Substances List. Sodium citrate is listed in  
128 CAN/CGSB-32.311-2015 – Organic production systems - Permitted substances lists sodium citrate as a  
129 food additive, as a food grade cleaner, disinfectant and sanitizer (without removal), and as a cleaner,  
130 disinfectant and sanitizer (removal is mandatory).

**131 CODEX Alimentarius Commission, Guidelines for the Production, Processing, Labelling and Marketing**  
**132 of Organically Produced Foods (GL 32-1999) -**

133 According to Codex Alimentarius GL 32-1999, sodium citrate is not permitted for use in organic production  
134 of food of plant origin, but is permitted for use in organic production in processed food of animal origin as  
135 follows: butter milk (plain) (stabilizer only); dairy-based drinks, flavored and/or fermented (e.g., chocolate  
136 milk, cocoa, eggnog, drinking yoghurt, whey-based drinks); fermented milks (plain), heat-treated after  
137 fermentation (stabilizer only); renneted milk (stabilizer only); condensed milk and analogues (plain)  
138 (stabilizer only); cream (plain) and the like (stabilizer only); milk powder and cream powder (plain)  
139 (stabilizer only); unripened cheese (stabilizer only); processed cheese (emulsifier only); dried whey and  
140 whey products, excluding whey cheeses; processed comminuted meat, poultry, and game products,  
141 restricted to sausages; to be used in pasteurization of egg whites only in the following: egg products.

**142 European Economic Community (EEC) Council Regulation, EC No. 834/2007 and 889/2008**

143 Commission Regulation (EC) No 889/2008 lays down rules for the use of sodium citrate. It is permitted in  
144 the production of processed organic food for preparation of foodstuffs of animal origin, but not permitted  
145 in foodstuffs of plant origin.

**146 Japan Agricultural Standard (JAS) for Organic Production –**

147 The Japanese Agricultural Standard for Organic Processed Foods allows the use of sodium citrate limited  
148 to dairy products or albumen and sausage as low temperature pasteurization. The Japanese Agricultural  
149 Standard for organic livestock does not allow the use of sodium citrate. The Japanese Agricultural  
150 Standard for organic plants does not allow the use of sodium citrate. The Japanese Agricultural Standard  
151 for organic feeds does not allow the use of sodium citrate.

**152 International Federation of Organic Agriculture Movements (IFOAM) -**

153 The IFOAM norms allow the use of sodium citrates for production of processed foods as an additive and as a  
154 processing aid.

**155 Evaluation Questions for Substances to be used in Organic Crop or Livestock Production**

156 **Evaluation Question #1: Indicate which category in OFPA that the substance falls under: (A) Does the**  
157 **substance contain an active ingredient in any of the following categories: copper and sulfur**  
158 **compounds, toxins derived from bacteria; pheromones, soaps, horticultural oils, fish emulsions, treated**  
159 **seed, vitamins and minerals; livestock parasiticides and medicines and production aids including**  
160 **netting, tree wraps and seals, insect traps, sticky barriers, row covers, and equipment cleansers? (B) Is**  
161 **the substance a synthetic inert ingredient that is not classified by the EPA as inerts of toxicological**  
162 **concern (i.e., EPA List 4 inerts) (7 U.S.C. § 6517(c)(1)(B)(ii)? Is the synthetic substance an inert**  
163 **ingredient which is not on EPA List 4, but is exempt from a requirement of a tolerance, per 40 CFR part**  
164 **180?**

165 As an anticoagulant used in processing blood for blood meal, sodium citrate may be considered a  
166 production aid (7 USC 6517(c)(1)(B)(i)). Sodium citrate is the sodium salt of citric acid prepared from citric  
167 acid by neutralizing citric acid with sodium hydroxide or sodium carbonate followed by a crystallization  
168 step. Commonly available forms are anhydrous or dehydrate.

169 **Evaluation Question #2: Describe the most prevalent processes used to manufacture or formulate the**  
170 **petitioned substance. Further, describe any chemical change that may occur during manufacture or**  
171 **formulation of the petitioned substance when this substance is extracted from naturally occurring plant,**  
172 **animal, or mineral sources (7 U.S.C. § 6502 (21)).**

173 Sodium citrate is produced by addition of sodium carbonate monohydrate to a hot aqueous solution of  
174 citric acid. The resulting solution is then evaporated until crystallization has taken place. Another synthetic  
175 method used for producing sodium citrate is decomposing calcium citrate with an alkali metal salt  
176 (sodium). [Citric acid](#) production is described in a 2015 NOP technical report. Some microorganisms can  
177 produce sodium citrate directly during fermentation. Sodium citrate is directly recovered from citric acid  
178 fermentation broth by removing impurities at pH 9-13 and concentrating the resulting fluid at pH 10-13.  
179 The organisms for this type of fermentation are yeasts, such as *Candida*, *Bretanomyces*, *Debaryomyces*,  
180 *Hanseula*, *Koeckera*, *Torulopsis*, *Pichia*, *Triospora*, *Saccharomyces* and bacteria such as *Corynebacterium* and  
181 *Arthrobacter* (Tsuda et al., 1975). In another process, *Yarrowia lipolytica* ferments glycerol-containing  
182 biodiesel waste and produces sodium citrate, which is filtered from the culture after pH adjustment to 7-8  
183 with NaOH (Kamzolova et al., 2015).

184 **Evaluation Question #3: Discuss whether the petitioned substance is formulated or manufactured by a**  
185 **chemical process, or created by naturally occurring biological processes (7 U.S.C. § 6502 (21)).**

186 Sodium citrate is synthetic. It is currently classified as synthetic in 205.605(b). The use of sodium citrate as  
187 an anticoagulant depends on the application and process approach. When a farm animal is slaughtered  
188 blood is released in an amount equivalent to 6-7% of the lean meat of the carcass based on total protein.  
189 Many cultures consider meat animal blood a food (Wismer-Pedersen, 1988). In addition to uses in food,  
190 animal blood has many uses in feed, laboratory, medical, industrial and fertilizer applications (Ockerman  
191 and Hansen, 2000).

192 Blood is composed of two primary fractions separable by centrifugation: the plasma and the red blood  
193 cells. Red blood cells contain the protein hemoglobin (Fernando, 1992). A relatively small quantity of white  
194 blood cells and platelets are also present. Plasma contains the proteins albumin, globulin and fibrinogen.  
195 Fibrinogen is involved in clotting. Greater than 80% of raw blood is water (Fernando, 1992).

196 The efficiency of blood collection depends on the animal, the length of time permitted for bleeding and the  
197 method for collection (Fernando, 1992). Blood from slaughterhouse animals is usually collected in one of  
198 two ways depending upon the application. It can be collected hygienically for use in foods and products,  
199 such as hemoglobin and plasma proteins. A closed draining system can be used where blood from the  
200 slaughterhouse animal is not exposed to air and is drained directly from the body of the animal; for  
201 example, using a hollow knife connected to vacuum piping (Fig 3). Blood for food or therapeutic  
202 applications must come with a guarantee that it is sourced from veterinary-approved disease-free animals  
203 and is free from contamination. In alive and healthy animals, blood is "sterile", in the sense that it can be  
204 consumed. However, collecting blood hygienically requires additional equipment, adds cost and slows  
205 down any slaughtering line speed (Bah et al., 2013). Transport of harvested blood to a processing facility  
206 may also require the use of a refrigerated tanker truck (Fernando, 1992). Another method for collecting  
207 animal blood is open draining into buckets, trays or onto the floor. This method is particularly susceptible  
208 to contamination and not likely to be suitable for food or therapeutic applications. Rather blood collected  
209 this way is used industrially or for fertilizer production. In any case it is prudent to consider collecting  
210 blood as a byproduct rather than discarding it. Blood has a high chemical oxygen demand (COD) (500,000  
211 milligrams O<sub>2</sub>/liter). As a result, disposal of large quantities of slaughterhouse blood can cause  
212 environmental problems (Kostic et al., 2013).

213 After bleeding clotting takes place in three to ten minutes depending on the environmental temperature.  
214 Clotting is caused by the conversion of soluble fibrinogen in the blood to insoluble fibrin by the enzyme  
215 thrombin. Clotting does not occur in circulating blood because there are natural anticoagulants present in  
216 intact blood vessels. Clotting may or may not be desirable for processing depending on the use of collected  
217 blood (Fig 4). Some of the commercial processes used for production of blood meal, which is used as a soil  
218 amendment in organic crop production require blood to clot to separate the solids from water. However,  
219 blood is a complex product and some value-added production streams may require the use anticoagulants  
220 to permit collection and separation of erythrocytes and protein products in addition to the production of  
221 blood meal. Clotting can be efficiently inhibited with the addition of 0.2 % sodium citrate during blood  
222 collection (Lewisohn, 1915). Regulations for the use of sodium citrate in the food and pharmaceutical  
223 industry vary from country to country (Ockerman and Hansen, 2000). Sodium citrate removes ionic  
224 calcium from solution. Ionic calcium is necessary for clotting to occur (Kingston et al., 2001).

233

234

Fig. 4 Treatment of slaughterhouse blood for specific uses (from Fernando, 1992)

- 235 Sodium citrate is an allowed synthetic substance for use as an ingredient in organic processing (205.605(b)).  
236 Sodium citrate is not on the National List for use in organic crop production.  
237
- 238 **Evaluation Question #4: Describe the persistence or concentration of the petitioned substance and/or its  
239 by-products in the environment (7 U.S.C. § 6518 (m) (2)).**
- 240 Sodium citrate is the sodium salt of citric acid. It is highly mobile in the environment and partitions to the  
241 aquatic compartment. Sodium citrate is rapidly degraded microbiologically in sewage works, in surface  
242 waters and in soil. Generally, citric acid and its salts have not been judged by the EPA or Organization for  
243 Economic Cooperation to be substances that present a hazard to the environment (EPA, 1992; OECD, 2001).
- 244 **Evaluation Question #5: Describe the toxicity and mode of action of the substance and of its  
245 breakdown products and any contaminants. Describe the persistence and areas of concentration in the  
246 environment of the substance and its breakdown products (7 U.S.C. § 6518 (m) (2)).**
- 247 Sodium citrate is of low acute toxicity to freshwater fish, daphnia, algae and marine species. Similarly,  
248 sodium citrate has no obvious toxic potential against protozoans and many species or strains of bacteria  
249 including activated sludge micro-organisms (EPA, 1992; OECD, 2001).
- 250 **Evaluation Question #6: Describe any environmental contamination that could result from toxicity due  
251 to the petitioned substance's manufacture, use, misuse, or disposal (7 U.S.C. § 6518 (m) (3)).**
- 252 Sodium citrate is produced biologically by the same submerged fermentation process with starch/sucrose-  
253 based media as citric acid, but is neutralized in the presence of appropriate alkaline solutions (e.g., sodium  
254 hydroxide or sodium carbonate) and crystallized. Several agricultural waste residues and by-products are  
255 used as production substrates for sodium citrate production including molasses, fruit pomace waste, wheat  
256 bran, coffee husk, and cassava bagasse. Most of the substrates would otherwise be composted, but  
257 represent a value-added component in sodium citrate production (Dhillon et al., 2011). Fermentation waste  
258 can be composted. However, the production of 1 ton of citric acid produces 40 tons of acidic wastewater  
259 with a high chemical oxygen demand. Production wastewater can be treated by biohydrogen production,  
260 electrochemical oxidation, membrane filtration and anaerobic and aerobic bacterial digestion. Studies are  
261 underway to repurpose this wastewater stream for methane production (Zhang et al., 2014).
- 262 **Evaluation Question #7: Describe any known chemical interactions between the petitioned substance  
263 and other substances used in organic crop or livestock production or handling. Describe any  
264 environmental or human health effects from these chemical interactions (7 U.S.C. § 6518 (m) (1)).**
- 265 Sodium citrate is very soluble in water and microbiologically degradable. As an anticoagulant for  
266 slaughterhouse blood, sodium citrate is used at a concentration of 0.2-0.4% and may become a component  
267 of the meat processing effluent. As a low concentration component ( $\leq 0.08\%$ ) of blood meal used as a soil  
268 amendment it is expected for sodium citrate to become a metabolite of soil bacteria.
- 269 **Evaluation Question #8: Describe any effects of the petitioned substance on biological or chemical  
270 interactions in the agro-ecosystem, including physiological effects on soil organisms (including the salt  
271 index and solubility of the soil), crops, and livestock (7 U.S.C. § 6518 (m) (5)).**
- 272 Sodium nitrate is used at a concentration of 0.2-0.4% in whole fresh blood. Blood is mostly composed of  
273 water ( $\geq 80\%$ ). Thus, dried blood meal is expected to contain no more than  $\sim 0.1\%$  sodium citrate. Potential  
274 organic fertilizer nitrogen sources vary in nitrogen cost and nitrogen mineralization rate. Blood meal has a  
275 nitrogen content of about 12% and 75% of organic carbon and nitrogen is mineralized after 8 weeks at 25°C.  
276 The rest can be found in humus components (Ciavatta et al., 1997). Blood meal is comparable to liquid  
277 fertilizers, e.g. liquid fish (Gaskell and Smith, 2007). It can be prepared by spray drying hemolyzed red  
278 blood cells from sodium citrate treated slaughterhouse blood and is a good soil amendment for the  
279 prevention of iron chlorosis in plants (Gruppo Farpro, 2017; Kalbasi and Shariatmadari, 1993). Mossbauer  
280 and electron paramagnetic spectra revealed that iron from the blood meal amendment is associated with  
281 the porphyrin heme group of hemoglobin. There is an advantage to application of iron in blood meal since  
282 it is bound to an organic moiety easing plant uptake of iron. However, when high  $\text{CaCO}_3$  is present in the  
283 soil, the iron bound porphyrin is likely to aggregate and cause the iron to be retained in the soil. Sodium  
284 citrate does not appear to negatively affect soil fertility (Yunta et al., 2013). As a fertilizer, blood meal  
285 produced using sodium citrate treated blood, provides sources of nitrogen, phosphorus, and calcium;

286 improves soil structure; promotes beneficial soil microorganisms; encourages earthworms; increases plant  
287 growth and yield; provides a balanced supply of nitrogen, phosphorus, and potassium, and organic matter  
288 including amino acids, albumin, globulin, cholesterol, and calcium; increases the growth promoters  
289 triconanol and gibberellic acid; reduces waterlogging plant stress and reduces plant stress recovery time  
290 (Quilty and Cattle, 2011). Application of blood meal as soil amendment causes soil electrical conductivity,  
291 organic matter and pH to increase (Citak and Sonmez, 2011).

292 **Evaluation Question #9: Discuss and summarize findings on whether the use of the petitioned**  
293 **substance may be harmful to the environment (7 U.S.C. § 6517 (c) (1) (A) (i) and 7 U.S.C. § 6517 (c) (2) (A)**  
294 **(i)).**

295 Sodium citrate is the sodium salt of citric acid. Citric acid has been produced for many years in high  
296 volumes and added to processed food and beverages, used in pharmaceutical preparations and in  
297 household cleaners as well as in special technical applications (OECD, 2000). Citric acid is a well-known  
298 component of carbohydrate metabolism in living organisms, and is found naturally in soil and water. It  
299 degrades readily when in contact with a variety of microorganisms that are found in soil, natural waters  
300 and sewage treatment systems (EPA, 1992). Citric acid is of low acute toxicity to freshwater fish, daphnia  
301 and algae and a few marine species, e.g. crabs, green algae, diatoms. Similarly, citric acid has no obvious  
302 toxic potential against protozoans and many species or strains of bacteria including activated sludge micro-  
303 organisms. Monitoring data has shown that while raw sewage contains up to 10 milligrams citrate/liter,  
304 background concentrations in river water range between < 0.04 and maximally 0.2 mg/l, and between  
305 0.025 and 0.145 mg/l in Atlantic coast surface seawater. However, these water concentrations for citrate do  
306 not only arise from manmade citric acid. Citric acid is extremely widespread in plant and animal tissues  
307 and fluids and every single eukaryotic organism produces citric acid and excretes part of it to the  
308 environment. Based on a large volume of available data collected by the Organization for Economic  
309 Development citric acid was not judged to be a substance that presents a hazard to the environment  
310 (OECD, 2000).

311 **Evaluation Question #10: Describe and summarize any reported effects upon human health from use of**  
312 **the petitioned substance (7 U.S.C. § 6517 (c) (1) (A) (i), 7 U.S.C. § 6517 (c) (2) (A) (i) and 7 U.S.C. § 6518**  
313 **(m) (4)).**

314 Industrial releases of citric acid can occur from the production site and its use in industrial processes.  
315 Consumers are directly exposed to citric acid or its salts in diluted concentrations in many products from  
316 soft drinks and processed food to common household cleaners, detergents and washing powders. There is  
317 no acceptable daily intake level. Occupational exposure may occur during manufacturing and processing  
318 of sodium citrate. There is no recommended occupational exposure level. Citric acid has a low acute  
319 toxicity by oral application in both rat (LD50 = 3,000– 12,000 mg/kg, 3 different values) and mouse (LD50 =  
320 5,400 mg/kg). General effects consisted of physiological disturbances (acidosis and calcium deficiency),  
321 while “high” doses caused nervous system effects as well as severe damage to the stomach mucosa. By  
322 subcutaneous application, LD50 values of 5,500 mg/kg in rats and 2,700 mg/kg in mice have been  
323 reported. Injection of citric acid by various routes in rats, mice and rabbits (no doses stated) caused nervous  
324 system, lung, spleen and liver effects that were in part attributed to acidosis and calcium deficiency.  
325 Ingestion of a single dose of 25 g of citric acid by a woman (corresponding to approx. 417 mg/kg) caused  
326 vomiting and near dying in one reported case. Volunteers given oral doses of potassium or magnesium  
327 citrate corresponding to approx. 4.7 g of citric acid did not suffer any overt gastrointestinal effects. Injection  
328 of large volumes of citrated blood during transfusion may lead to hypocalcaemia and changes in blood  
329 composition with concomitant nausea, muscle weakness, breathing difficulties and even cardiac arrest.  
330 Sodium citrate is a strong irritant to the eyes and a moderate skin irritant (OECD, 2000).

331 **Evaluation Question #11: Describe all natural (non-synthetic) substances or products which may be**  
332 **used in place of the petitioned substance (7 U.S.C. § 6517 (c) (1) (A) (ii)). Provide a list of allowed**  
333 **substances that may be used in place of the petitioned substance (7 U.S.C. § 6518 (m) (6)).**

334 There are not many non-synthetic substances or products that may be used as anticoagulants for  
335 slaughterhouse blood processing. Such substances would need to prevent the proenzyme, thrombinogen  
336 from converting to thrombin, prevent the proenzyme fibrinogen from converting to fibrin and/or prevent  
337 the web-like matrix formation of fibrin in the blood, e.g. chelating calcium ions. Naturally, the glycoprotein  
338 heparin serves as an anticoagulant in blood vessels and in the intestines. Because heparin is chemically

339 extracted from animal byproducts and crystallized as a salt, it is not considered non-synthetic. Heparin is  
340 prohibited for use in livestock care (205.105(a)). A mixture of phosphates containing 22%  $\text{Na}_2\text{HPO}_4$ ,  
341 22%  $\text{Na}_4\text{P}_2\text{O}_7$ , 16%  $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$  and 40% NaCl at a rate of 10 grams/liter is an effective anticoagulant,  
342 although they are not included in section 205.601 of the National List and not allowed for use in organic  
343 crop production. Sodium oxalate may also be used as an anticoagulant, but it is considered poisonous and  
344 may not be appropriate for application to soil as a soil amendment (Ockerman and Hansen, 2000).

345 Plant, bacterial and fungal proteolytic enzymes such as papain, bromelin, trypsin, fibrinolysin, bacterial  
346 protease N, bacterial protease P, bacterial protease S and others have been used in place of anticoagulants  
347 industrially to extract proteins from blood. These enzymes act proteolytically on fibrin to prevent clotting  
348 and support a process to provide good quality protein (Quaglia and Massacci, 1982).

349 **Evaluation Question #12: Describe any alternative practices that would make the use of the petitioned**  
350 **substance unnecessary (7 U.S.C. § 6518 (m) (6)).**

351 In practice, blood flows from an animal after it is stuck with a knife (Fig 3). The blood can be collected in  
352 troughs or tanks beneath the animal. If a hollow knife is used with an anticoagulant injected at knifepoint  
353 whole blood can be pumped aseptically to tanks for further processing. Further processing can include  
354 conventional use in foods and feed if the animal carcass from which it came is approved by a meat  
355 inspector. An anticoagulant can also be added to the open troughs or tanks to facilitate additional  
356 separations, e.g. whole blood may be separated into red blood cells and plasma and the fractions are dried  
357 or processed separately. Separated red blood cells can be dried or spray dried for use in blood meal for  
358 fertilizer.

359 Without added anticoagulant, clotted blood is collected and processed by separating clotted blood from the  
360 water component, drying and grinding. (Stevenson and Lloyd, 1979). Blood that is collected in this way can  
361 be directly batch dried. In this drying process, water may be added to the blood as it is charged into a batch  
362 cooker that simply dries the blood to 2-10% moisture. In batch coagulation followed by batch drying raw  
363 blood is first coagulated with steam. The coagulum is then separated by draining off liquid before it is  
364 moved to a drier for drying. Continuous coagulation before drying is the most commonly used process. In  
365 each of these processes, an anticoagulant is optional (Fernando, 1992). Rapid chilling of blood to 1-2° C (34-  
366 36°F) will prevent coagulation without an anticoagulant, but blood will coagulate when the temperature  
367 increases. Agitation and refrigeration are routinely used where blood must be stored or transported prior  
368 to processing to prevent microbial growth. Vigorous stirring of blood causes fibrin to adhere to the stirring  
369 rod and prevent coagulation, however this process damages red blood cells (Ockerman and Hansen, 2000).  
370 This process called defibrination removes the potential of blood to clot. Defibrinated blood is available  
371 commercially.

372 Blood is an edible byproduct of meat processing. Edible blood is regulated in the same way as other meat  
373 products and must be inspected prior to consumption by the supervising agency. Edible by-products are  
374 perishable and must be chilled quickly after slaughter and processed or moved into retail trade (Ricke et  
375 al., 2012). One certified organic slaughterhouse in the US provides blood for human consumption  
376 (Kaufman, 2015; Organic Integrity Database (Operation Profile (7360000108) updated on 12/14/2017)).  
377 Sodium citrate may be added to fresh whole blood collected for human consumption. Dried blood as a  
378 food grade ingredient may contain less than 0.1% of sodium citrate by weight. Producers must usually  
379 follow hazard analysis critical control point (HAACP) principles, clean equipment after each use and  
380 document the origin of each batch of blood. Regardless of whether or not an anticoagulant is used, storage  
381 of fresh blood is maintained with stirring and chilling in closed containers (Food Safety Authority of  
382 Ireland, 2013). Chilling in this case in this case also inhibits the growth of bacterial contaminants.

383 Labels for blood meal advertised for use as fertilizer do not normally indicate the animal origin of the  
384 product, the condition of the animals, whether an anticoagulant (e.g. sodium citrate) was used or the  
385 process that was used for production. Thus, unless specifically stated on the label, it may not be possible to  
386 determine if sodium citrate was used as an anticoagulant during the collection of blood to be used for  
387 blood meal. There are no organic production operations listed in the organic integrity database for 2017  
388 that are certified to provide organically produced blood for food or fertilizer.

389 Slaughterhouse blood processing end products' technical and sanitary requirements determine their costs  
390 and production efficiencies. Lots that are rejected for a higher priced product may be acceptable for another

391 less expensive product. Specifically, reliable sourcing of blood meal prepared from slaughterhouse blood  
392 that was not treated with sodium citrate may require traceability and segregation of the non-treated  
393 material after it was withdrawn from animals independently of how the blood meal was prepared. Such  
394 information could be provided on the product label or obtained from a process verification audit.
